### Approximation of functions and data

#### Exercise I (MATLAB)

Let us consider a digital measuring instrument sampling a signal expressed by the function  $g(x)$  for  $x \in I = [a, b] = [0, 1]$ , where  $g(x) = 10x^2$ . The output of the instrument is affected by ground noise and can be represented by a function  $f(x) = g(x) + \varepsilon(x)$ , where  $|\varepsilon(x)| \leq 1$ . In MATLAB, we consider the following commands:

```
g = @(x) 10 * x.^2; % True signal
f = @(x) g(x) + 2*rand(size(x))-1; % Instrument output
```

The ground noise  $\varepsilon(x)$  is represented by the command `2*rand(size(x))-1`, which returns a random vector (with values in  $[-1, 1]$ ) of the same size of  $x$ . Note that the function `f` returns a different realization each time (even if the variable  $x$  is the same).

- Compute the polynomial  $\Pi_n f(x)$  of degree  $n = 9$  interpolating  $f(x)$  at  $n + 1$  equally spaced nodes in  $I$  by using the MATLAB functions `polyfit` and `polyval`. Then, by using the same nodes, compute the least-squares polynomial  $\tilde{f}_m(x)$  of degree  $m = 2$  approximating  $f(x)$ . Plot in the same figure the functions  $f(x)$  and  $g(x)$  and the polynomials  $\Pi_n f(x)$  and  $\tilde{f}_m(x)$ . Which method produces better representations of the original signal between the polynomial interpolation and the least-squares approximation?
- Use the polynomials  $\Pi_9 f(x)$  and  $\tilde{f}_2(x)$  to extrapolate the value of  $f(x)$  in  $x = 2$ . Compare and discuss the results obtained.
- The repetition of the measure would typically return a different signal  $f(x)$  in output due to the presence of noise. We already represented this situation in MATLAB; indeed, at each call of the function `f`, we obtain different values due to the use of the function `rand`. In this manner we can study the stability of the polynomials  $\Pi_n f(x)$  and  $\tilde{f}_m(x)$  by analyzing the variation of the results using a different set of couples  $(x_i, f(x_i))$ ,  $i = 0, \dots, n = 9$ . What do we observe if we repeat the points a) and b)? Discuss the results obtained.

#### Exercise II (MATLAB)

Let us consider the function  $f(x) = e^{-x^2/2}$  in the interval  $I = [a, b] = [-5, 5]$ .

- By using the MATLAB function `interp1`, compute and plot the piecewise linear interpolating polynomials  $\Pi_1^H f(x)$  of  $f(x)$  in  $n$  sub-intervals of size  $H = \frac{b-a}{n}$  where  $n = 2, 7, 12, 22, 27, 32$ . Perform a graphical comparison of the interpolating polynomials with  $f(x)$ .
- Following point a), compute the errors  $e_1^H(f) := \max_{x \in I} |f(x) - \Pi_1^H f(x)|$  corresponding to the piecewise linear interpolating polynomials  $\Pi_1^H f(x)$  for  $n = 2, 3, \dots, 32$  sub-intervals of the same size  $H$ , and plot them in a figure as a function of  $n$  by using the semi-logarithmic scale. Motivate the result obtained.
- The not-a-knot interpolating cubic spline  $s_3(x)$  can be computed in MATLAB by using the command `spline` (see `help spline`). Compute the spline  $s_3(x)$  approximating  $f(x)$  by subdividing the interval  $I$  in  $n = 7$  sub-intervals of the same size and plot it in comparison with  $f(x)$  and the corresponding piecewise linear interpolating polynomial  $\Pi_1^H f(x)$ . Finally, plot the errors  $e_{s_3}(f) := \max_{x \in I} |f(x) - s_3(x)|$  as a function of  $n$  for  $n = 2, 3, \dots, 32$ .

### Exercise III (Theoretical)

Let us consider the following function  $f(x) = \frac{1}{1+x}$  in the interval  $I = [a, b] = [0, 5]$ .

- We consider the piecewise linear interpolation polynomial of  $f(x)$ , say  $\Pi_1^H f(x)$ , on  $n$  sub-intervals of the same size  $H = \frac{b-a}{n}$ . Compute the minimum number of these sub-intervals such that the error associated to the piecewise linear interpolation polynomial  $\Pi_1^H f(x)$  is smaller than  $10^{-3}$ .
- Repeat point a) by considering now the natural interpolating cubic spline of  $f(x)$ , say  $s_3(x)$ , in place of  $\Pi_1^H f(x)$ . With this aim, recall that for  $f \in C^4(I)$ :

$$\max_{x \in I} |f^{(r)}(x) - s_3^{(r)}(x)| \leq C_r H^{4-r} \max_{x \in I} |f^{(4)}(x)|, \quad \text{for } r = 0, 1, 2,$$

and some positive constants  $C_r$  depending on  $r$ . For simplicity we assume that  $C_r \simeq 1$ .

What is the minimum number of sub-intervals of the same size ensuring that the error associated to the first derivative of  $s_3(x)$  is smaller than the same tolerance  $10^{-3}$ ?

- Let us consider the following nodes:  $x_0 = 0$ ,  $x_1 = 1/2$ ,  $x_2 = 1$ . Calculate the least-squares polynomial of degree  $m = 1$ , say  $\tilde{f}_1(x) = a_0 + a_1 x$ , which approximates  $f(x)$ . Proceed by finding the coefficients  $a_0$  and  $a_1$  which minimize the following functional:

$$\Phi(a_0, a_1) = \sum_{i=0}^2 [f(x_i) - \tilde{f}_1(x_i)]^2 = \sum_{i=0}^2 [f(x_i) - a_0 - a_1 x_i]^2.$$

### Exercise IV (MATLAB)

The left ventricle is the chamber of the heart responsible for pumping oxygenated blood into the major organs. We have obtained a time series of  $n + 1 = 11$  data couples  $\{(t_j, V_j)\}_{j=0}^n$  describing the volume  $V_j$  ( $\text{cm}^3$ ) of a specific left ventricle at time  $t_j$  (s):

$j$ [–]	0	1	2	3	4	5	6	7	8	9	10
$t_j$ [s]	0.00	0.07	0.14	0.21	0.28	0.35	0.42	0.49	0.56	0.63	0.70
$V_j$ [ $\text{cm}^3$ ]	194	184	177	156	142	160	168	166	170	178	187

We wish to find an interpolating curve, say  $I_t V(t)$ , that describes the volume  $V(t)$  of the left ventricle as it contracts during the heartbeat. Since the volume of the ventricle  $V(t)$  can be considered as a periodic function of the time  $t$  with period  $T$  equal to the length of the heartbeat (here  $T = 0.77$  s), we decide to use *trigonometric interpolation*.

- a) By using the MATLAB command `interpft`, interpolate the data couples by means of trigonometric interpolation and evaluate the interpolant on  $m \cdot 11$  equally spaced points; use e.g.  $m = 100$ . Plot the data couples and the trigonometric interpolant  $I_t V(t)$  on the same figure. Then, by using the trigonometric interpolant  $I_t V(t)$  of  $V(t)$ , evaluate the *ejection fraction* (percentage of volume of blood ejected during one heartbeat) defined by the formula:

$$E_f = \frac{\max_{t \in [0, T]} I_t V(t) - \min_{t \in [0, T]} I_t V(t)}{\max_{t \in [0, T]} I_t V(t)}.$$

- b) We observe that in a real ventricle the volume  $V(t)$  first decreases monotonically during the contraction of the muscle (for  $t \in [0, 0.3]$  s) and then increases monotonically during the relaxation of the muscle (for  $t \in (0.3, 0.77]$  s) due to the presence of two valves that block the flow in the wrong direction. This property is not obeyed by the interpolant  $I_t V(t)$  due to the presence of the erroneous data couple  $(t_7, V_7) = (0.49, 166)$ , which is likely consequence of a measurement error. Since in trigonometric interpolation we assume that the nodes are equally spaced, we can not simply remove the couple  $(t_7, V_7)$  from the data set. Instead, we define a new series of data couples  $\{(t_j, V_j)\}_{j=0}^n$  by replacing the erroneous value with the average of its two nearest neighbors:

$$\tilde{V}_j := \begin{cases} V_j & \text{if } j \neq 7, \\ \frac{V_{j-1} + V_{j+1}}{2} & \text{if } j = 7. \end{cases}.$$

Compute the corrected trigonometric interpolant  $I_t \tilde{V}(t)$ , evaluate the interpolant on  $m \cdot 11$  equally spaced points for  $m = 100$ , and plot it in the same figure with  $I_t V(t)$ . Compute also the new estimated ejection fraction:

$$\tilde{E}_f = \frac{\max_{t \in [0, T]} I_t \tilde{V}(t) - \min_{t \in [0, T]} I_t \tilde{V}(t)}{\max_{t \in [0, T]} I_t \tilde{V}(t)}.$$

Are the results considerably different compared to the ones obtained in part a)?

### Exercise V (Theoretical)

We consider the function  $f : [0, 2\pi] \rightarrow \mathbb{R}$ :

$$f(x) := \begin{cases} \frac{1}{\pi}x, & x \in [0, \pi], \\ 2 - \frac{1}{\pi}x, & x \in (\pi, 2\pi]. \end{cases}$$

- a) Calculate the Lagrange polynomial interpolating  $f(x)$  at the nodes  $x_0 = 0$ ,  $x_1 = \frac{2}{3}\pi$ ,  $x_2 = \frac{4}{3}\pi$ , and  $x_3 = 2\pi$ .

- b) Find the least-squares polynomial of degree 1 (regression line) approximating  $f(x)$  evaluated at the nodes  $x_0 = 0$ ,  $x_1 = \frac{2}{3}\pi$ ,  $x_2 = \frac{4}{3}\pi$ , and  $x_3 = 2\pi$ .
- c) Repeat point b) for the least-squares polynomial of degree 2 approximating  $f(x)$ .
- d) We observe that  $f(x)$  is periodic. Calculate the trigonometric interpolant of  $f(x)$  by evaluating the function at the nodes  $x_0 = 0$ ,  $x_1 = \frac{2}{3}\pi$ , and  $x_2 = \frac{4}{3}\pi$ .

**Exercise VI (Theoretical)**

Given  $B \in \mathbb{R}^{n \times m}$ ,  $\mathbf{y} \in \mathbb{R}^n$ , and  $\mathbf{a} \in \mathbb{R}^m$ , with  $m < n$ , and the following linear system:

$$B\mathbf{a} = \mathbf{y},$$

show that the least square solution  $\tilde{\mathbf{a}} \in \mathbb{R}^m$  satisfies the normal equations

$$B^T B \tilde{\mathbf{a}} = B^T \mathbf{y}.$$
